## 1 Who am I? Introduction to myself

- Follow me on github! <https://github.com/TomatoCream>
- Linux user for 5 years now
  - Ubuntu
  - Proxmox
  - ArchLinux
  - Centos (server management)

### 1.1 My interests

- AI, ML
- Functional programming and abstraction (what the hell is so good about this?)
- Philosophy
  - occam's razor <peekture>

### 1.2 For whom is this talk for?

- Linux users! Sorry windows users
  - But not really (departs away from a unix way of doing things)
- Show you what functional programming can do?
  - purity?
  - referential transparency?
- State management
- DevOps
- Images, Docker, VM, Clusters

## 2 The big problem

- Has anyone ever used some sort of package management system?

### 2.1 Some modern day package management systems

Package manager	Distributions
apt, apt-get	Debian, Ubuntu
rpm, yum	Redhat, Centos
pacman	ArchLinux
brew	MacOS

### 2.2 What about sub ecosystems?

Package manager	???
pip, virtualenv, pipenv	Python2,3(???)
npm, yarn	Nodejs
cabal, stack, hackage	Haskell :)
go?	go?
brew	MacOS
use-package, vim, fish, zsh	...

### 2.3 How to make a package manager?

- What are the basic parts that we need?

### 2.4 How to make a package manager?

build dependencies	What do I need to build the program?
runtime dependencies	What .so shared objects do I need?
configurations	What in /etc/... config files

- essentially think of it as a graph, whenever we upgrade or install a package, we are mutating a node on this graph to point to something else.

### 2.5 Problems with modern package management

[https://wiki.debian.org/DontBreakDebian#Don.27t\\_make\\_a\\_FrankenDebian](https://wiki.debian.org/DontBreakDebian#Don.27t_make_a_FrankenDebian)

<b>Contents</b>
1. Advice For New Users On Not Breaking Their Debian System
1. Don't make a FrankenDebian
2. Don't use GPU manufacturer install scripts
3. Don't suffer from Shiny New Stuff Syndrome
4. 'make install' can conflict with packages
5. Don't blindly follow bad advice
6. Read The Fantastic Manuals
7. Don't blindly remove software
8. Read package descriptions before installing
9. Take notes
10. Some safer ways to install software not available in Debian Stable
1. Backported packages
2. Building from source
3. Using chroot, containers, and virtual machines
1. Flatpak
2. Snap
11. Get the most out of peer support resources
2. See Also

## 2.6 TODO Why imperative is bad? What is so imperative about installing packages?

referential transparency

## 2.7 Are you familiar with DEPENDENCY HELL?

- [https://www.reddit.com/r/ProgrammerHumor/comments/75txp4/nodejs\\_dependency\\_hell\\_visualized\\_for\\_the\\_first/?utm\\_source=share&utm\\_medium=web2x](https://www.reddit.com/r/ProgrammerHumor/comments/75txp4/nodejs_dependency_hell_visualized_for_the_first/?utm_source=share&utm_medium=web2x)
- <https://github.com/vector-im/riot-web/network/dependencies>

## 2.8 All types of "DEPENDENCY HELL"

[https://miro.medium.com/max/984/0\\*7ezJ0tYUkI5zyqWU.png](https://miro.medium.com/max/984/0*7ezJ0tYUkI5zyqWU.png)

- { DLL, dependency, npm, cabal } hell, different names for the same demon
- conflicting dependency
  - shared components like library links `cuda.7.so` vs `cuda.6.so`

- multiple version side by side and roll backs
- possible solutions
  - set of stable packages like Debian or haskell stack snapshots

## 2.9 Not Atomic 01

- kill upgrades half way
  - packages left in a semi updated state
  - sometimes need to manually remove lock files

COMMAND	PID	USER	FD	TYPE	DEVICE	SIZE/OFF	NODE	NAME
dpkg	29329	root	3uW	REG	8,7	0 262367		/var/lib/dpkg/lock

## 2.10 Not Atomic 02

- can be fixed but kinda troublesome.

2

You can give a try to fix your problem using **Recovery Mode** if none of the method works for you. If you are using wired connection then no problem, for wireless connection I'm not sure whether it will work or not, because I never tried to enable network in Recovery Mode when using wireless connection. Although you can give it a try.

- When your system starts chose **Recovery Mode** (2nd option in grub menu).
- From the Menu just go to **Grub** option, it will give a message like **Updating grub will mount your system in read/write mode**. Just chose **yes** to mount your system in read/write mode. It will update your grub and will exit from **Grub** menu.
- chose **network** option it may enable your network.
- Then chose **dpkg** menu from the list, chose **yes** for all.
- Finally chose **root** option and login. Execute following commands one after another:

```
# apt-get autoremove
# apt-get autoclean
# apt-get update
# apt-get -f install
# apt-get dist-upgrade
# apt-get upgrade
```

Then reboot your system and check whether your issues are fixed or not. Run this command to reboot:

```
# reboot
```

Reply if something goes wrong.s

## 2.11 Whats bad about imperative summary?

- No referential transparency

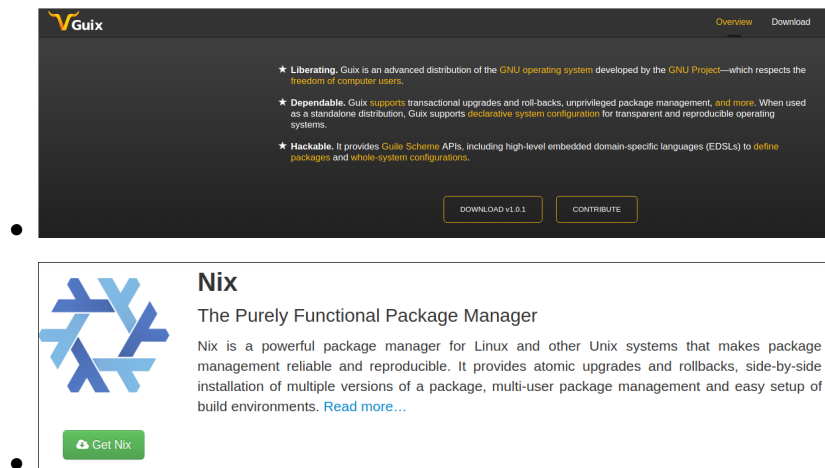

- cannot point to older versions of the same thing
- Dependency hell
  - conflicting dependencies
- Not atomic upgrades
  - unknown state if break half way

These problems are really similar to the problems with imperative languages! like `JAVA` and people have already made solutions for them like how `Haskell` does. We could learn a thing or two from them.

### 3 What it should/could/would have been?

- Imagine now that we implemented all the things of a functional programming language to create a functional package management system?
- What can we do with this?

#### 3.1 GUIX vs Nix

#### 3.2 Introducing Nix Package Management

- solves all of the problems above
  - No referential transparency

- \* cannot point to older versions of the same thing
- Dependency hell
- Not atomic upgrades
- \* unknown state if break half way

### 3.3 Main mechanism

- referential transparency
  - install everything in path `/nix/store/{hash}-name`
  - via symlinking

### 3.4 What you get for free with this mechanism?

- no `sudo`
- easy revert and roll back
- 2 different version can run at the same time
- same **development** environment as the **runtime** environment!
  - `nix-shell`

#### 3.4.1 no sudo, where is my sudo?

- linux was developed as a `time sharing` system
- many users were expected to share a single computer.
- thus to manage conflicts, a `super user`, `root` was required to install and manage packages

```
nix-env -iA nixos.figlet
```

#### 3.4.2 easy revert, rollback

```
figlet "I am here!"
```

```
nix-env --rollback
```

```
figlet "are you still here?"
```

### **3.5 Going all the way, NixOS**

- whole system management via Nix
  - Version controlled operating system
  - show OS reboot

### **3.6 There are actually 2 players**
